The callable contract

Status: R0, first slice implemented. This is the root contract for calls in the lowered path. It separates a **reference** from a **call**, so a name that resolves to a value can never be silently invoked as a word, and a word call can never silently return a value. The suite is 1530 checks (1488 examples, 42 properties).

The rule

A call site is one of:

- a **lexical closure** bound by a static `Let`/`Lambda`; lowering emits `PushSlot; CallClosure`;
- a **word** (builtin, vocabulary word, user word, generic, word metaobject, host word, or book word); lowering emits `CallWord`.

A bare word reference is a value reference: a statically bound name lowers to `PushSlot`; a free name lowers to `CallWord` only when it denotes a word.

The lowered/compiled path is **strict**. If a `CallWord` reaches a runtime lexical binding, the program is malformed for that path; it is a named refusal (`a lowered word call cannot resolve a runtime lexical binding`), never a silent value push. The interpreter keeps its own dynamic `let`/`define` semantics.

Why

`CallWord` used to serve both a word call and a name reference. A call to a name that was not in the static environment lowered to `CallWord`; at runtime, if the frame held that name, `Evaluator.executeWord` pushed the value. A function that called itself or a later definition returned its own closure with exit code zero. The book loader now admits recursive groups (D194); this contract also protects the lowered path when a dynamic binding reaches a word call.

The durable target

The full callable model replaces the static/dynamic split with one resolver:

- one `Callable` kind (builtin, closure, unit, word metaobject, generic/method, host word, book word, F# primitive);
- one `Invoke` operation with arity and effect checks;
- one guard/epoch cache;
- one refusal vocabulary.

That model is backlog item R0′s durable form; this slice is its enforceable boundary. Recursion markers, host words, book words, and type signatures all use the same answer to "what did this name resolve to, and is this a call?"

Tests

1. a word call through the lowered bridge still works;
2. a lowered call that reaches a runtime lexical binding is a named refusal;
3. an earlier book definition call still works;
4. a self, forward, or mutual book call is a real group call (D194).

Non-goals

This slice does not add the unified `Callable` DU. The `logic`/`cycle` definition words and book recursion build on this boundary: book recursion is D194, and the definition words are D195.
